PREFACE

This report contains a summary of the data compiled during the evaluation of the test compound. The report is organized to present the results in a concise and easily interpretable manner. The first part contains items I-IX. Items I-IV provide sponsor and compound identification information, type of assay, and the protocol reference number. All protocol references indicate a standard procedure described in the Litton Bionetics, Inc. "Screening Program for the Identification of Potential Mutagens and Carcinogens." Item V provides the initiation and completion dates for the study, and Item VI provides identification of supervisory personnel. Item VII identifies the tables and/or figures containing the data used by the study director in interpreting the test results. The interpretation itself is in Item VIII. Item IX provides the conclusion and evaluation.

The second part of the report describes the materials and procedures employed in conducting the assay. This part of the report also contains evaluation criteria used by the study director, and any appendices. The evaluation criteria are included to acquaint the sponsor with the methods used to develop and analyze the test results.

All test and control results presented in this report are supported by fully documented raw data which are permanently maintained in the files of the Department of Genetics and Cell Biology or in the archives of Litton Bionetics, Inc., 5516 Nicholson Lane, Kensington, Maryland 20795.

I. SPONSOR: W.R. Grace

II. MATERIAL (TEST COMPOUND): GENETICS ASSAY NUMBER: 5123

A. Identification: FHP 3000 H3 (11601-10)

B. Date Received: May 15, 1980

C. Physical Description: Viscous yellow liquid

III. TYPE OF ASSAY: Ames Salmonella/microsome Mutagenesis Assay

IV. PROTOCOL NUMBER: 401

V. STUDY DATES:

A. Initiation: May 30, 1980

B. Completion: June 13, 1980

VI. SUPERVISORY PERSONNEL:

A. Study Director: D.R. Jagannath, Ph.D.

B. Laboratory Supervisor: Sibyl Goode

VII. RESULTS:

The results of this assay are presented in Table 1.

VIII. INTERPRETATION OF RESULTS:

The test compound was examined for mutagenic activity in a series of in vitro microbial assays employing Salmonella indicator organisms. The compound was tested directly and in the presence of liver microsomal enzyme preparations from Aroclor-induced rats.

DOSE RANGE

The dose range employed for the evaluation of this compound was from $0.5~\mu g$ to $5000~\mu g$ per plate.

TOXICITY

The test material did not exhibit toxicity with any of the indicator strains used in this assay.

INTERPRETATION OF RESULTS (continued): VIII.

The results of the tests conducted on the test material in the absence of a metabolic activation system were negative. The test with TA-1538 was repeated because of low solvent control values observed in the initial test. The repeat test was negative. The test with TA-1537 was repeated at 100 to 5000 µg dose levels because of the increase in number of revertants observed at 1000 µg dose in the initial test. The repeat test performed in duplicate was negative.

The results of the tests conducted on the test material in the presence of a rat liver activation system were negative. The test with TA-1535 was repeated because of the unacceptable solvent control values observed in the initial test. The repeat test was negative.

IX. CONCLUSIONS:

The test material FHP 3000 H3 (11601-10) did not exhibit genetic activity in any of the assays conducted in this evaluation and was considered not mutagenic under these test conditions according to our evaluation criteria.

AMES SALMONELLA/MICROSOME PLATE ASSAY

OBJECTIVE

The objective of this study is to evaluate a test material for mutagenic activity in a bacterial assay with and without a mammalian S9 activation system.

RATIONALE

The Salmonella typhimurium strains used at LBI are all histidine auxotrophs by virtue of mutations in the histidine operon. When these histidine-dependent cells are grown in a minimal media petri plate containing a trace of histidine, only those cells that revert to histidine independence (his+) are able to form colonies. The trace amount of histidine allows all the plated bacteria to undergo a few divisions; this growth is essential for mutagenesis to occur. The his+ revertants are easily scored as colonies against the slight background growth. The spontaneous mutation frequency of each strain is relatively constant; but when a mutagen is added to tre agar, the mutation frequency is increased 2- to 100-fold. Cells which grow to form colonies on the minimal media petri plates are therefore assumed to have reverted, either spontaneously or by the action of a test substance to his+ genotype.

3. MATERIALS

A. Indicator Microorganisms

The <u>Salmonella</u> typhimurium strains used in this assay were obtained from Dr. Bruce Ames, University of California at Berkeley.¹⁻⁵ The following 5 strains are routinely used.

Strain	Gene	Addi	Mutation Type		
Designation	Affected	Repair	LPS	R Factor	Detected
TA-1535	<u>his</u> G	Δ <u>uvr</u> B	rfa	-	Base-pair substitution
TA-1537	his C	Δ uvr B	rfa		Frameshift
TA-1538	his D	Δ uvr B	rfa		Frameshift
TA-98	his D	Δ uvr B	rfa	pKM101	Frameshift
TA-100	<u>his</u> G	Δ <u>uvr</u> B	rfa	рКМ101	Base-pair substitution

All of the above strains have, in addition to the mutation in the histidine operon, a mutation (rfa-) that leads to defective lipopoly-saccharide coat, a deletion that covers genes involved in the synthesis of vitamin biotin (bio-) and in the repair of ultraviolet (uv) - induced DNA damage (uvrB-). The rfa mutation makes the strains more permeable to many large molecules. The uvrB- mutation decreases repair of some types of chemically or physically damaged DNA and thereby enhances the strain's sensitivity to some mutagenic agents. The resistant transfer factor plasmid (R factor) pKM101, in TA-98 and TA-100 is believed to cause an increase in error-prone DNA repair that leads to many more mutations for a given dose of most mutagens⁵. In addition, plasmid pKM101 confers resistance to the antibiotic ampicillin, which is a convenient marker to detect the presence of plasmid in the cells.

All indicator strains are kept at 4°C on minimal medium plates supplemented with a trace of biotin and an excess of histidine. The plates with plasmid-carrying strains contain in addition ampicillin (25 μ g/ml), to ensure stable maintenance of plasmid pKM101. New stock culture plates are made every two months from the frozen master cultures or from single colony reisolates that were checked for their genotypic characteristics (his, rfa, uvrB, bio) and for the presence of plasmid. For each experiment, an inoculum from the stock culture plates is grown overnight at 37°C in nutrient broth (0xoid CM67) and used.

B. Media

The bacterial strains were cultured in Oxoid Media #2 (nutrient Broth). The selective medium was Vogel Bonner Medium E with 2% glucose⁷. The overlay agar will consist of 0.6% purified agar with 0.5 mM histidine, 0.05 mM biotin and 0.1M NaCl according to the methods of Ames et al.6

C. Activation System

(1) S9 Homogenate

A 9,000 x g supernatant prepared from Sprague-Dawley adult male rat liver induced by Aroclor 1254 (described by Ames et al. 6) was purchased from Bionetics Laboratory Products, Litton Bionetics, Inc. and used in this assay.

(2) S9 Mix

Components	Concentration per Milliliter S9 Mix
NADP (sodium salt)	4 µmoles
NADP (sodium salt) D-glucose-6-phosphate	5 µmoles
MgC1 ₂	8 umoles
KC1	33 µmoles
Scdim phosphate buffer	
12 7.4	100 µmoles
Organ home genate from rat	
Organ home-genate from rat liver (S9 fraction)	100 µliters

BIONETICS

4. EXPERIMENTAL DESIGN

A. Dosage Selection

All tests are run at a minimum of four concentrations. In the standard plate test, at least six dose levels of the test material, dissolved in a suitable solvent, are added to the test system. The standard test doses are 0.005, 0.01, 0.1, 1.0, 5.0 and 10.0 μ liters per plate for liquids and 0.5, 1.0, 10.0, 100.0, 500.0 and 1000.0 μg per plate for solids. Additional doses may be employed in the tests if toxicity is observed at the three highest doses. When no toxicity is observed, additional concentrations may be employed up to 50 μ liters or 5000 μg per plate.

B. Mutagericity Testing

The procedure used is based on the paper published by Ames et al. 6 and is performed as follows:

(1) Nonactivation Assay

To a Sterile 13 x 100 mm test tube placed in a 43° C water bath the following is added in order:

- (a) 2.00 ml of 0.6% agar containing 0.05 mM histidine and 0.05 mM biotin.
- (b) 0.05 ml of a solution of the test chemical to give the appropriate dose.
- (c) 0.1 ml 0.2 ml of indicator organism/s.
- (d) 0.50 ml of 0.01M phosphate buffer, pH 7.4.

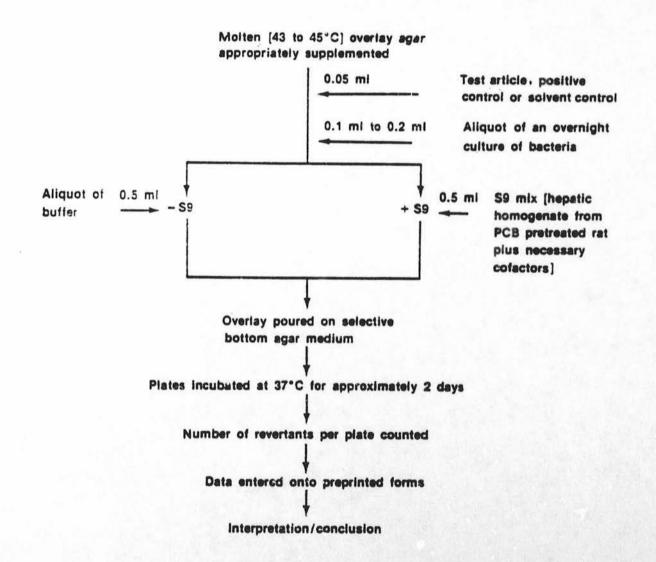

This mixture is swirled gently and then poured nto minimal agar plates (see 3B, Media). After the top agar has set, the plates are incubated at 37°C for approximately 2 days. The number of his+ revertant colonies growing on the plates is counted and recorded.

(2) Activation Assay

The activation assay is run concurrently with the nonactivation assay. The only difference is the addition of 0.5 ml of S9 mix (see 3C:2, Activation System) to the tubes in place of 0.5 ml of phosphate buffer which is added in nonactivation assays. All other details are similar to the procedure for nonactivation assays.

FIGURE 1

REVERSE MUTATION ASSAY [Agar Incorporation Method]

5. EVALUATION CRITERIA

Statistical methods are not currently used, and evaluation is based on the criteria included in this protocol.

Plate test data consists of direct revertant colony counts obtained from a set of selective agar plates seeded with populations of mutant cells suspended in a semisolid overlay. Because the test material and the cells are incubated in the overlay for approximately 2 days and a few cell divisions occur during the incubation period, the test is semiquantitative in nature. Although these features of the assay reduce the quantitation of results, they provide certain advantages not contained in a quantitative suspension test:

The small number of cell divisions permits potential mutagens to act on replication DNA, which is often more sensitive than nonreplicating DNA.

The combined incubation of the test article and the cells in the overlay permits constant exposure of the indicator cells for approximately 2 days.

A. Surviving Populations

Plate test procedures do not permit exact quantitation of the number of cells surviving chemical treatment. At low concentrations of the test material, the surviving population on the treatment plates is essentially the same as that on the negative control plate. At high concentrations, the surviving population is usually reduced by some fraction. Our protocol will normally employ several doses ranging over two or three log concentrations. This does not apply to spot tests and tests performed on fabrics and like materials which are tested at a single concentration.

B. Dose-Response Phenomena

The demonstration of dose-related increases in mutant counts is an important criterion in establishing mutagenicity. A factor that might modify dose-response results for a mutagen would be the selection of doses that are too low (usually mutagenicity and toxicity are related). If the highest dose is far lower than a toxic concentration, no increases may be observed over the dose range selected. Conversely, if the lowest dose employed is highly cytotoxic, the test material may kill any mutants that are induced, and the test material will not appear to be mutagenic.

C. Control Tests

Positive and negative control assays will be conducted with each experiment and will consist of direct-acting mutagens for nonactivation assays and mutagens that require metabolic biotransformation in activation assays. Negative controls will consist of the test material solvent in the overlay agar together with the other essential components. The negative control plate for each strain will give a reference point to which the test data will be compared. The positive control assay will be conducted to demonstrate that the test systems are functional with known mutagens.

D. Evaluation Criteria for Ames Assay

Because the procedures to be used to evaluate the mutagenicity of the test material are semiquantitative, the criteria to be used to determine positive effects are inherently subjective and are based primarily on a historical data base. Most data sets will be evaluated using the following criteria.

(1) Strains TA-1535, TA-1537 and TA-1538

If the solvent control value is within the normal range, a test material that produces a positive dose response over three concentrations with the highest increase equal to three times the solvent control value will be considered to be mutagenic.

(2) Strains TA-98 and TA-100

If the solvent control value is within the normal range, a test material that produces a positive dose response over three concentrations with the highest increase equal to twice the solvent control value for TA-98 and TA-100 will be considered to be mutagenic.

(3) Pattern

Because TA-1535 and TA-100 are both derived from the same parental strain (G-46) and because TA-1538 and TA-98 are both derived from the same parental strain (D3052), to some extent there is a built-in redundancy in the microbial assay. In general, the two strains of a set respond to the same mutagen and such a pattern is sought. Generally, if a strain responds to a mutagen in nonactivation tests, it will do so in activation tests.

(4) Reproducibility

If a test material produces a response in a single test that cannot be reproduced in additional runs, the initial positive test data lose significance.

E. <u>Evaluation Criteria for Toxicity</u>

(1) Complete toxicity

When there are no revertants observed on the plate(s) treated with the test compound, the test compound will be defined as toxic to all or any of the indicator strains at that particular dose(s).

(2) Slight toxicity

When there are fifty per cent or less number of revertants on the plate(s) treated with the test compound as compared to the solvent control plate(s), the test compound will be defined as slightly toxic to all or any of the indicator strains at that particular dose(s).

F. Relation Between Mutagenicity and Carcinogenicity

It must be emphasized that the Ames <u>Salmonella/Microsome Plat Assay</u> is not a definitive test for chemical carcinogens. It is recognized, however, that correlative and functional relations have been demonstrated between these two endpoints. The results of comparative tests on 300 chemicais by McCann et al. show an extremely good correlation between results of nicrobial mutagenesis tests and <u>in vivo</u> rodent carcinogenesis assays.

All evaluations and interpretation of the data to be presented in the final report will be based only on the demonstration, or lack, of mutagenic activity.
